

PreventionofPlay (PoP) –HLD	2
Prevention of Play (PoP): Non-Functional Requirements	7

PREVENTION-OF-PLAY (POP) –HLD

1. Overview

Key enhancements include:

2. Application Architecture

2.1 Key Components

2.2 Application Architecture Diagram

Flow Summary:

1. Overview

The Prevention-of-Play (PoP) capability has transitioned from the legacy CID platform to a modern, centralised Salesforce-based system. This new architecture supports the consistent application of PoP and Exclusion rules across jurisdictions, enables reliable replication to downstream systems, and provides stronger auditability, scalability, and integration flexibility.

Key enhancements include:

- Unified patron restriction processing across NSW and QLD.
- Salesforce Service Cloud as the central system of record for PoP cases and restrictions.
- Platform Events for real-time communication with Azure-based integration services.
- Automated restriction propagation to downstream systems such as Synkros, Loyalty, Payments, and CIAM.
- Enhanced security, compliance tracking, and audit history through Salesforce Shield and robust permission design.

2. Application Architecture

The PoP architecture follows a modular, event-driven model using Salesforce as the core case management and restriction orchestration engine. Integration with Azure enables scalable, asynchronous communication with downstream platforms.

2.1 Key Components

Layer	Component	Description
Frontend	Salesforce Service Console	Used by staff to initiate PoP Apply, Revoke, or Contravention cases and manage associated work orders.

Core Application	Case Management	Core case and work order handling functionality within Salesforce.
	Salesforce Shield	Provides data encryption at rest and audit logging of user activity and field-level changes.
	PoP Automation	Automation flows that publish Platform Events, initiate FormAssembly API calls, and handle business logic.
	Restriction Reconciliation Automation	Updates restriction statuses in Salesforce based on acknowledgment responses from downstream systems.
External App	FormAssembly	Handles dynamic document generation and e-signature workflows. Invoked via Salesforce API calls during relevant PoP case stages.
Integration	Platform Events (Outbound)	Carries data such as action type, restriction code, status, and patron ID to Azure Logic Apps.
	API Flow	Triggers document generation and e-signature processes via FormAssembly.
	Platform Events (Inbound)	Receives acknowledgments from Azure for processing back in Salesforce.
	Event Bus	Internal mechanism within Salesforce that manages event routing and delivery.

Middleware	Azure Logic Apps & Functions	Subscribes to Platform Events, orchestrates calls to downstream systems (e.g., Synkros, CIAM), manages retries and responses.
Downstream Systems	Synkros, PingOne (Identity & Access), Smart Button, MDM, NeoFace	Systems that enforce or remove restrictions based on PoP actions.
Monitoring	Dynatrace	Provides telemetry and operational monitoring for Azure Logic Apps and integrations.

2.2 Application Architecture Diagram

Flow Summary:

- **Case Initiation** – An authorised user creates a Prevention-of-Play (Apply, Revoke, or Contravention) case in Salesforce.
- **Work Order Execution** – Corresponding Work Orders are automatically created and tracked to manage jurisdictional restrictions and case processing requirements.

- **Document Generation and E-Signature** – Based on the case workflow, Salesforce invokes FormAssembly via secure API to generate, distribute, and capture signed exclusion or revocation documents.
- **Restriction Notification** – Once case actions are validated, Salesforce publishes a **Platform Event** containing restriction details such as action type, status, Stop Code, and Patron ID.
- **Azure Processing** – Azure Logic Apps subscribe to the Platform Event, process the message, and orchestrate restriction updates across downstream systems (e.g. Synkros, CIAM/PingOne, Smart Button, SFMC, etc.).
- **Acknowledgment Handling** – Azure alone provides the acknowledgment response back to Salesforce confirming message processing or delivery status. Each downstream system (Synkros, PingOne, etc.) completes its respective restriction processing independently and synchronises outcomes back to **MDM** or **ACE**, which in turn updates Salesforce via existing data pipelines.
- **Azure Monitoring Feedback** – Azure continuously monitors specific downstream attributes not currently synced via MDM or ACE — such as Stop Code changes in **Synkros** and Status updates in **PingOne** — and notifies Salesforce when these changes occur to maintain data alignment.
- **Restriction Update** – Restriction records and related Contact or Case data in Salesforce are updated based on acknowledgement or change events received through Azure or the existing MDM/ACE sync processes.
- **Audit and Monitoring** – All user and system actions are audited through **Salesforce Shield**, while integration and processing health are monitored via **Dynatrace** within Azure.

PREVENTION OF PLAY (POP): NON-FUNCTIONAL REQUIREMENTS

Non-Functional Requirements define the *quality attributes* of the Prevention of Play (PoP) system. They describe how the system performs, secures, scales, integrates, and operates rather than what it does functionally. In PoP, NFRs are critical because the solution spans multiple regulated jurisdictions (NSW and QLD), integrates with several downstream systems (MDM, Synkros, NeoFace, PingOne, ACE), and supports strict governance and compliance obligations.

Each NFR category below — from Platform & Performance to Infrastructure & Deployment — ensures that the PoP system meets operational expectations across scalability, resilience, data integrity, compliance, and user experience.

The tables include three columns: **NFR**, **Detailed Explanation**, and **Design Coverage**.

Platform & Performance

NFR	Detailed Explanation	Design Coverage
Regulatory report distribution (scheduled export)	Regulatory and operational reports must be available on fixed cadences (daily/weekly/monthly) for compliance and audit needs, while Salesforce reports remain live for business use.	Azure Logic App runs on a defined schedule to call the Salesforce Analytics API and export XLSX files to SharePoint . Salesforce dashboards remain real-time; scheduling only governs external distribution.
Near real-time event processing	Platform Events must propagate updates quickly to downstream systems to ensure exclusions, revocations, and restrictions are enforced across venues with minimal delay.	Salesforce publishes Platform Events; a Flow subscribes and performs an external service call to a secure REST endpoint in Azure. Salesforce retries failed calls up to three times and provides a manual retry button. Azure orchestrates downstream updates via Logic Apps, Functions, and Service Bus.
Scalability and throughput	The system must handle large migration volumes (>100k CID	Bulk API 2.0 and asynchronous Apex handle high-volume data

	records) and concurrent users without degradation.	operations. Azure Service Bus partitioning and Logic App concurrency controls maintain downstream scalability.
Availability and fault tolerance	The platform must remain operational and recover gracefully from component failures without disrupting business operations.	Salesforce multi-AZ architecture provides enterprise availability. Azure Logic Apps, Functions, and Service Bus use retry and DLQ mechanisms for resiliency.

Security, Privacy & Compliance

NFR	Detailed Explanation	Design Coverage
Data encryption	Protect all data in transit and at rest to comply with privacy and regulator standards.	<i>Salesforce data encrypted at rest with Shield Platform Encryption;</i> SharePoint libraries and Azure storage are encrypted at rest. All data in transit uses TLS 1.2+.
Role-based access	Enforce least-privilege access to protect sensitive data.	Permission Sets manage access by persona (CLM, Safer Gambling, Surveillance, Financial Crime). Record-level sharing applies jurisdictional filters.
Regulatory SLA tracking and audit compliance	The system must enforce and monitor SLA windows for regulator reports without embedding business workflow logic.	Salesforce tracks SLA milestones and alerts for statutory submissions (e.g., 5-day internal review, 7-day furnish). Audit logs ensure regulatory traceability.
Sequential exclusion numbering	Exclusion orders must be sequential and gap-free per state to satisfy regulator audit standards.	Apex logic generates jurisdiction-specific sequences (NSW-###, QLD-###) using row-level locking to prevent duplication and maintain audit accuracy.

Audit trail	Every data change and action must be traceable.	Field Audit Trail and Event Monitoring record all CRUD actions and report exports; sequential numbering reinforces trace integrity.
-------------	---	---

Data & Integration

NFR	Detailed Explanation	Design Coverage
Integration reliability	Integrations must guarantee delivery, retries, and consistency during transient failures.	Platform Events trigger secure REST callouts to Azure; Salesforce retries up to three times on failure with manual retry support. Azure manages orchestration reliability through Logic Apps, Functions, and Service Bus with DLQ.
Data retention	Retention must align with corporate and regulatory policies.	<i>Salesforce audit data retained under Shield configuration;</i> archival handled per the approved retention policy.

Reporting & Analytics

NFR	Detailed Explanation	Design Coverage
Export formats (XLSX, PDF)	Reports must be exportable for external audit and regulator use.	Azure Logic App calls the Salesforce Analytics API to export XLSX to SharePoint. PDF letters and orders are generated within Salesforce and attached to Exclusion records.
Regulatory evidence packs	Generate letters and orders for regulator submission; photos are excluded.	Automated Flows create PDF letters and orders only, stored as Salesforce Files for review and export when required.

Access control	Restrict report and file visibility to authorised users only.	Salesforce folder permissions and SharePoint library permissions (Azure AD) enforce access controls.
----------------	---	--

User Experience

NFR	Detailed Explanation	Design Coverage
Consistent UI across states	Uniform experience for all jurisdictions to reduce training overhead.	Dynamic Lightning Pages adjust fields and layouts by jurisdiction but maintain a consistent structure.
No dual-keying	Prevent duplicate entry across systems.	Automation ensures exclusion data syncs across connected applications without manual re-entry.
Template and signature management	Enable digital form submission and secure signatures.	FormAssembly integrated digital signature supports letter/order completion; PDFs stored as Salesforce Files (optional SharePoint publication).

Auditability & Monitoring

NFR	Detailed Explanation	Design Coverage
Change history	Maintain configuration history for audit and environment traceability.	Salesforce Setup Audit Trail provides configuration change logs. Source control and CI/CD tooling (as approved by the platform team) manage deployment versioning and rollback traceability.
Event monitoring	Capture user activity for anomaly detection and audit.	<i>Shield Event Monitoring exports logs;</i> Azure Dynatrace monitors Logic Apps, Functions, and Service Bus for failures and alerts operations.
Integration logs	Maintain transparency for API events and integrations.	Salesforce Integration Log object captures Platform Event ID, correlation

		IDs, timestamps, and error details; Dynatrace logs Azure-side failures.
Reconciliation	Ensure exclusion data consistency across Salesforce and NeoFace.	Scheduled job compares Salesforce Exclusion records with NeoFace enrolments; mismatches reported to Surveillance.

Infrastructure & Deployment

NFR	Detailed Explanation	Design Coverage
Environment segregation	Maintain separate environments for development, testing, and production.	Salesforce Sandboxes (Dev, SIT, UAT) and distinct Azure resource groups per environment.
Deployment pipeline	Ensure traceable, auditable deployments with change governance and rollback capability.	Salesforce deployment process uses the organisation-approved CI/CD framework managed by the Platform Delivery team. All deployments are tracked with approvals, versioning, and rollback options per release management policy.
Backup and archival	Guarantee recoverability and long-term compliance retention.	ACE Data Lake performs daily incremental backups and long-term encrypted archival per the approved retention policy .
Monitoring and alerts	Provide proactive detection and escalation for failures.	Dynatrace monitors Logic Apps, Service Bus, and Functions for errors; alerts routed to the support distribution list/rota.
